

Bayesian Statistics Homework 1

Gelman et al., *A Weakly Informative Default Prior Distribution For Logistic and Other Regression Models* (2008)

Roberto Corti

April 7, 2021

Logistic regression: we have some problems...

In some cases, Maximum Likelihood estimates of the coefficients can lead to unstable results.

The need of (weak) prior information

Adding a prior distribution over regression's coefficient can regularize unstable results.

Which kind of prior do we use?

- Non-informative prior
- Fully informative prior

The aim is to provide *weakly informative priors*

- provide minimal information
- able to give regularized coefficient estimates

General assumptions for weakly-informative priors

What prior information can be assumed for a generic model?

"For logistic regression, a change of 5 in the logistic scale moves a probability from 0.01 to 0.5, or from 0.5 to 0.99"

We rarely encounter this kind of situations, thus we are willing to assign for $\pi(\beta_i)$ low probabilities for values outside $[-5, 5]$

General assumptions for weakly-informative priors

In order to have a default prior that could be used in many different contexts, it has to be defined over a commonly interpretable scale.

It is required to *standardize* the input variables:

- For binary variables, inputs must have 0 mean and they have to differ 1 in their lower and upper values.
- Other variables must have 0 mean and standard deviation of 0.5.

General assumptions for weakly-informative priors

Which probability distribution can be used for this prior?

- prior independence: $\pi(\beta) = \pi(\beta_0) \cdot \pi(\beta_1) \cdot \dots \cdot \pi(\beta_J)$
- t-Student family: flat-tailed distributions, easy and stable computations.

Typical choices can be:

- for the coefficient terms β_1, \dots, β_J , model as a likelihood of a binomial trial with half successes and half failures:
 $\pi(\beta_i) = t_{\nu=1}(\theta = 0, s = 2.5)$ (Cauchy distribution).
- for the constant term β_0 , allow a success probability between 10^{-9} and $1 - 10^{-9}$ for units that are average in all the inputs:
 $\pi(\beta_0) = t_{\nu=1}(\theta = 0, s = 10)$ (Cauchy distribution).

A tool to use weakly-informative priors in R

bayesglm

- **Goal:** get MAP estimates β_{MAP} and $V_{\beta_{MAP}}$
- **Computation:** Considering the prior distribution for each coefficient as a mixture of normals with unknown scale σ_i

$$\pi(\beta_i) = \pi(\beta_i|\sigma_i)\pi(\sigma_i) = \mathcal{N}(\mu_i, \sigma_i^2)\text{inv-}\chi^2(\nu_i^2, s_i^2)$$

estimates of β_{MAP} and $V_{\beta_{MAP}}$ are obtained in a iterative way:

- for a fixed σ , approximate the priors as $\pi(\beta_i) \approx \mathcal{N}(\mu_i, \sigma_i^2)$ and get $\hat{\beta}$ by using weighted least squares.
- determine the expected value of the log-posterior density $\log p(\beta, \sigma|X, y)$ and maximize it with respect to σ in order to get to get the estimate $\hat{\sigma}$

Applications of bayesglm (1)

FIG. 2. The left column shows the estimated coefficients (± 1 standard error) for a logistic regression predicting the probability of a Republican vote for president given sex, race, and income, as fit separately to data from the National Election Study for each election 1952 through 2000. [The binary inputs female and black have been centered to have means of zero, and the numerical variable income (originally on a 1–5 scale) has been centered and then rescaled by dividing by two standard deviations.]

Applications of bayesglm (2)

Dose, x_i (log g/ml)	Number of animals, n_i	Number of deaths, y_i
-0.86	5	0
-0.30	5	1
-0.05	5	3
0.73	5	5

```
# from glm:
               coef.est coef.se
(Intercept) -0.1      0.7
z.x          10.2      6.4
  n = 4, k = 2
residual deviance = 0.1, null deviance = 15.8 (difference = 15.7)

# from bayesglm (Cauchy priors, scale 10 for const and 2.5 for other coef):
               coef.est coef.se
(Intercept) -0.2      0.6
z.x           5.4      2.2
  n = 4, k = 2
residual deviance = 1.1, null deviance = 15.8 (difference = 14.7)
```

FIG. 3. Data from a bioassay experiment, from Racine *et al.* (1986), and estimates from classical maximum likelihood and Bayesian logistic regression with the recommended default prior distribution. In addition to graphing the fitted curves (at top right), we show raw computer output to illustrate how our approach would be used in routine practice.

FIG. 4. A logistic regression fit for missing-data imputation using maximum likelihood (top) and Bayesian inference with default prior distribution (bottom). The classical fit resulted in an error message indicating separation; in contrast, the Bayes fit (using independent Cauchy prior distributions with mean 0 and scale 10 for the intercept and 2.5 for the other coefficients) produced stable estimates. We would not usually summarize results using this sort of table, however, this gives a sense of how the fitted models look in routine data analysis.

Applications of bayesglm (4)

FIG. 6. Mean logarithmic score (left plot) and Brier score (right plot), in fivefold cross-validation averaging over the data sets in the UCI corpus, for different independent prior distributions for logistic regression coefficients. Higher value on the y axis indicates a larger error. Each line represents a different degrees-of-freedom parameter for the Student-t prior family. BBR(l) indicates the Laplace prior with the BBR algorithm of Genkin, Lewis, and Madigan (2007), and BBR(g) represents the Gaussian prior. The Cauchy prior distribution with scale 0.75 performs best, while the performances of glm and brglm (shown in the upper-right corner) are so bad that we could not capture them on our scale. The scale axis corresponds to the square root of variance for the normal and the Laplace distributions.
